## Abstract

## Background

Publication of data from past field studies on invertebrate populations is of high importance, as there is much added value for them to be used as baselines to study spatiotemporal population and community dynamics in these groups. Therefore, a dataset consisting of occurrence data on epigaeic invertebrates collected in 1996 was standardised into the Darwin core format and cross-checked in order to make it publicly available following FAIR data principles. With publication, it can contribute to the biodiversity assessment of terrestrial invertebrates, thereby improving the availability and accessibility of much-needed historical datasets on macro-invertebrates.

Here, we present sampling event data on invertebrates from four grasslands taken out of agricultural production over the span of several decades, effectively displaying a chronosequence on the effects of agricultural extensification. The data were collected by means of a standardised sampling design using pyramid traps, pitfall traps and soil samples.

## New information

The raw data presented in this data paper have not been published before. They consist of 20,000+ records of nearly 70,000 specimens from 121 taxonomic groups. The data were collected using a standardised field study set-up and specimens were identified by taxonomic specialists. Most groups were identified up to family level, with eight groups identified up to species level. The occurrence data are complemented by information on plant composition, meteorological data and soil physical characteristics. The dataset has

been registered in the Global Biodiversity Information Facility (GBIF): <http://doi.org/10.15468/7n499e>

## Keywords

macro-arthropod survey, FAIR, Drentsche Aa, Anlooer Diepje, pyramid traps, pitfalls, Insecta, Araneae, Carabidae

## Introduction

In 1996, a nine-month sampling programme was carried out in four semi-natural grasslands in the northern part of the Netherlands with the aim of studying the effects of restoration management in former agricultural grasslands on the composition of below- and above-ground macro-invertebrate communities (Hemerik and Brussaard 2002). The four grasslands had been taken out of agricultural production after a period of intensive land use with high levels of nutrient amendments. At the time of sampling, the grasslands formed a restoration succession chronosequence of 7, 11, 24 and 29 years post-agricultural management. The main aim of this extensification programme was to restore former botanical richness by reducing nutrient levels in the soil (Berg and Hemerik 2004). The 1996 field sampling programme was set up in order to study the effects of restoration management on soil and ground-dwelling insects and spiders. It was suspected that changes in plant biomass production and alterations in litter quantity and quality stemming from the cessation of nutrient amendments would affect macro-invertebrate populations (Hemerik and Brussaard 2002). In addition, changes in vegetation structure, affecting microclimate, might have consequences for soil and ground-dwelling animal groups. Therefore, the researchers wanted to explore whether they could find differences in species diversity and composition of macro-invertebrates in the chronosequence.

The sampling plots were situated in the valley of the brooklet "Anlooer" Diepje, a much intact natural stream that forms part of the stream-valley system "Drentsche Aa," which is situated in the north-eastern part of the Netherlands in the Province of Drenthe (Liu et al. 2021). The fields surrounding the brooklet mainly consist of grasslands on loamy sand with a slightly acidic pH. The field study set-up involved the use of photoeklektors, also known as pyramid emergence traps, to sample airborne insects emerging as imago from the soil. Inside the tent of the pyramid emergence trap, two pitfall traps were dug into the ground. The soil that was dug out for placing the pitfalls was taken to the laboratory as soil samples to hand-sort for macro-invertebrates. The pyramid and pitfall traps were emptied weekly and moved randomly to a new location within the experimental plot every two weeks. Concurrently, a number of environmental variables were collected, including soil physical characteristics, soil temperature, as well as plant composition in the experimental plots (see Table 3 for a complete list). The sampling programme ran for 9 months, from 11 March until 23 December 1996.

This resulted in a dataset containing 21,282 records of 71,415 specimens that were caught during the nine months of sampling. All invertebrate species were identified up to at least the taxonomic level of order. In total, 121 taxonomic groups were distinguished (see Table 3). Terrestrial isopods (Isopoda), millipedes (Diplopoda), centipedes (Chilopoda), spiders (Araneae), harvestmen (Opiliones), click beetles (Elateridae), ground beetles (Carabidae) and weevils (Curculionidae/Brentidae) were identified up to species level.

In order to make it publicly accessible and (re)usable following FAIR data objectives, the data have been reviewed and cross-checked, as well as reorganised and standardised following the Darwin Core Standard (Wieczorek et al. 2012). The data have subsequently been published on GBIF (Hemerik and Creuwels 2023): <https://doi.org/10.15468/7n499e>

## Project description

**Title:** Macro-invertebrate survey Drentsche Aa 1996

**Personnel:** The original monitoring in 1996 was performed by Lia Hemerik ([ORCID 0000-0002-6892-2840](#)), together with taxonomic specialists who assisted with field work and identified specific species groups. The specialists were Arnold Spee and Theo van Dijk at Biologisch Station Wijster, Matty Berg ([ORCID 0000-0001-8442-8503](#)), Aart Noordam, Michael Traugeot and Theodoor Heijerman ([ORCID 0000-0002-9835-600X](#)). Standardising the dataset into Darwin Core format, cross-checking and publication of the data were performed by Lia Hemerik, assisted by Gijs M. Gerrits ([ORCID 000-0002-2315-9677](#)).

**Study area description:** The study area is located in the Drentsche Aa stream valley in the Province of Drenthe in the north-eastern part of the Netherlands (Fig. 1). The Drentse Aa is a 30 km<sup>2</sup> stream valley that has had a long history of agricultural exploitation with high levels of nutrient amendments and large alterations in the hydrological functioning of the Drentsche Aa stream and its tributaries, amongst which the Anlooer Diepje brooklet (Liu et al. 2021).

The four field study plots, all located along the banks of the Anlooer Diepje (Fig. 1), consisted of grass dominated vegetation, with *Lolium perenne* L., *Holcus lanatus* L., *Festuca rubra* L. and *Anthoxanthum odoratum* L., respectively, dominating in the chronosequence gradient. Management consisted of mowing once a year and the resulting hay was removed (Verschoor et al. 2001).

**Funding:** The reorganisation and publication of the data were made possible with a grant from NLBIF Netherlands Biodiversity Information Facility (grant number nlbif2021.003).

## **Sampling methods**

**Description:** The sampling programme was designed as a block field study set up within randomly selected experimental plots that were situated in the four selected grasslands of the chronosequence.

**Sampling description:** Within each of the four grasslands taken out of agricultural production, a plot measuring 30 m × 15 m was selected for the sampling to take place. Each plot was divided into three subplots (10 m × 15 m). One pyramid trap was placed within each of the subplots (i.e. 3 pyramid traps per experimental plot) and moved randomly across the subplot every two weeks. Inside the pyramid trap, two pitfall traps were placed (i.e. 6 pitfall traps per experimental plot), flush with the soil surface. The soil samples that were dug out (i.e. 12 soil samples per experimental plot) to accommodate the pitfall traps were collected in plastic bags and taken to the laboratory in Wageningen, stored at a temperature of 4°C and hand-sorted for soil macrofauna. Both pyramid and pitfall catches were collected on a weekly basis and soil samples on a two-weekly basis. In total, 12 pyramid traps were placed in the four plots, together with 24 pitfalls and 48 soil samples. See Table 1 for details.

The pyramid traps consisted of an opaque grey plastic ring (diameter of 56 cm). Above this ring, a gauze net made of white net fabric formed an inverted funnel-shaped dome. On top of the funnel dome, a white plastic trapping container in the shape of a ring functioned as a lightfall, bringing the total height of the pyramid trap to 80 cm (Fig. 2). The lightfall at the top contained a 2% formaldehyde ( $\text{CH}_2\text{O}$ ) solution, which served as a killing preservative. The pyramid traps were designed to catch flying insects that were either residing in the grass tussocks at the moment of placement or, more specifically, all insects that hatched from the soil during the time the trap was placed at each location. The pitfalls traps consisted of white plastic cups (0.5-litre yoghurt cups) with a diameter of 9 cm. The pitfalls were also filled with a 2% formaldehyde solution.

The specimens that were collected during sampling were stored in 70% ethanol, awaiting identification. The samples were destroyed after identification.

Table 1 provides an overview of the four plots and the trap numbers that were placed in each sampling plot.

Additional data were collected during the sampling programme on abiotic and botanical variables (see Table 2 for an overview). In addition, photographs of the research plots taken in 2021 are provided in Suppl. material 1, together with an overview of botanical composition in 1996 and in 2021.

Soil wet weight and dry weight were measured from the soil cores collected for placement of the pitfall traps. Furthermore, mean air temperature and total weekly precipitation in the week preceding a collection event were calculated from data available from the KNMI Meteorological Station Eelde (KNMI 2023), which is situated

approximately 11 km from the research site. The measurements are connected to the eventIDs and published as a MeasurementOrFact table.

As part of a study on nematodes in the same plots, Verschoor et al. (2001) collected abiotic data, namely bulk density, clay-silt percentage, pH-H<sub>2</sub>O, C-pool, N-pool and C/N ratio (see their table 1).

## Geographic coverage

**Description:** The study area was located in the Province of Drenthe, in the north-eastern part of the Netherlands, see Fig. 1. The plots O, B, C and K have their own pair of coordinates in GBIF. For the location of these plots on the map, we refer to Fig. 1.

**Coordinates:** 53.0449 and 53.0502 Latitude; 6.6661 and 6.6799 Longitude.

## Taxonomic coverage

**Description:** After collection, the specimens were identified by taxonomy specialists. All specimens were first sorted and identified to order level; true flies (Diptera) and beetles (Coleoptera) were further identified to family level by Lia Hemerik. Arnold Spee and Theo van Dijk assisted with field sampling and identification of the carabid beetles. Matty Berg identified terrestrial isopods (Isopoda), millipedes (Diplopoda) and centipedes (Chilopoda). Aart Noordam identified spiders (Araneae) and harvestmen (Opiliones). Michael Traugeot identified beetle larvae. Theodoor Heijerman identified weevils (Curculionidae/Brentidae).

Before publication of the dataset, all original taxonomical assignments were cross-checked with the Checklist Dutch Species Register – Nederlands Soortenregister (Creuwels and Pieterse 2023) and provided with a currently valid assignment when necessary. For a complete list of taxa included in the dataset, see Table 3.

## Temporal coverage

**Data range:** 1996-3-11 - 1996-12-23.

**Notes:** The field study started on 11 March 1996 and was finished on 23 December 1996. Sampling points were created each week when traps were collected.

## Usage licence

**Usage licence:** Other

**IP rights notes:** CC-BY-NC 4.0

## Data resources

**Data package title:** Macro-invertebrate survey Drentsche Aa 1996

**Resource link:** <https://www.gbif.org/dataset/a90782f8-e60e-46d8-82a4-e749b5cf69c3>

**Alternative identifiers:** [https://ipt.nlbif.nl/resource?r=drentse\\_a](https://ipt.nlbif.nl/resource?r=drentse_a); <https://doi.org/10.15468/7n499e>

**Number of data sets:** 1

**Data set name:** sampling event, 9 months in 1996, in the Drentsche A

**Data format:** txt

**Description:** The dataset has been published in the Global Biodiversity Information Facility platform, GBIF (Hemerik and Creuwels 2023). It is set up as a sampling event dataset with a three part structure; eventID, occurrenceID and MeasurementorFact. The dataset is published as a Darwin Core Archive (DwCA). The core data file contains 2,898 events with 21,887 occurrences. The GBIF IPT (Integrated Publishing Toolkit, Version 2.5.6) serves as the data repository. The table below provides descriptions of the column labels used. Note that labels are entered in alphabetical order, not in the order they are provided in the DwCA; MoF stands for Measurement-or-Fact extension.

Column label	Column description
basisOfRecord (Occurrence extension)	the specific nature of the data record.
class (Occurrence extension)	class name.
coordinateUncertaintyInMetres (Event core)	coordinate uncertainty.
country (Event core)	the country where the samples were taken, i.e. the Netherlands.
countryCode (Event core)	the code of the country where the samples were taken, i.e. NL.
decimalLatitude (Event core)	latitude of the field in which the sampling was performed.
decimalLongitude (Event core)	longitude of the field in which the sampling was performed.
endDayOfYear (Event core)	end of sampling period.
eventDate (Event core)	date of emptying the pitfall or lightfall or of taking a soil sample.
eventID (Event core, Occurrence extension, MoF)	unique identifier for each event per date, per pitfall, lightfall or soil sample.
eventRemarks (Event core)	remarks of emptying the pitfall or lightfall or of taking the soil sample.

family (Occurrence extension)	family name.
geodeticDatum (Event core)	the ellipsoid, geodetic datum or spatial reference system (SRS), upon which the geographic coordinates given in decimalLatitude and decimalLongitude are based.
identifiedBy (Occurrence extension)	a list of names of people who assigned the taxon to the subject.
individualCount (Occurrence extension)	number of recorded specimens per occurrenceID.
kingdom (Occurrence extension)	kingdom name.
lifestage (Occurrence extension)	life stage at which specimen was caught.
locality (Event core)	Drentsche Aa, one of the four fields.
locationRemarks(Event core)	different descriptions of the samples.
measurementAccuracy (MoF)	the accuracy of the measurement.
measurementDeterminedBy (MoF)	institution or person who has performed the measurement.
measurementRemarks (MoF)	comments on how the value is obtained.
measurementType (MoF)	description of the measurement, for example, minimum temperature in the week before, total precipitaion in the week before.
measurementUnit (MoF)	the unit of the measurement in SI units, e.g. g, mm.
measurementValue (MoF)	the measured/observed value.
occurrenceID (Occurrence extension)	unique identifier for each occurrence per species, per date, per pitfall, lightfall or soil sample.
occurrenceStatus (Occurrence extension)	a statement about the presence or absence, here present.
order (Occurrence extension)	order name.
ownerInstitutionCode (Event core)	the name (or acronym) in use by the institution having ownership of the object(s) or information referred to in the record.
parentEventID (Event core)	groups the eventIDs of 1 lightfall plus 2 pitfalls or of upper and lower soil samples.
phylum (Occurrence extension)	phylum name.
recordedBy (Occurrence extension)	institution by which specimen is identified and recorded.
sampleSizeUnit (Event core)	g resp. number.
sampleSizeValue (Event core)	size of soil sample, cumulation of individuals.
samplingEffort (Event core)	the amount of effort expended during sampling.
samplingProtocol (Event core)	the names and descriptions of the methods or protocols used during sampling.

scientificName (Occurrence extension)	genus + specificEpithet + author + publication year.
sex (Occurrence extension)	the sex of the biological individual.
startDayOfYear (Event core)	start of sampling period.
subfamily (Occurrence extension)	subfamily name.
taxonRank (Occurrence extension)	the taxonomic rank of the most specific name in the scientificName.
taxonRemarks (Occurrence extension)	Comments or notes about the taxon or name.
type (Event core)	event.
verbatimIdentification (Occurrence extension)	the taxonomic identification as it appeared in the original record.

## Acknowledgements

We thank Lijbert Brussaard for making it possible to conduct this monitoring at the Soil Biology Group of Wageningen University during 1996. We would like to thank Arnold Spee, Rijndert de Fluiter, Matty Berg, Theo van Dijk, Theodoor Heijerman, Aart Noordam and Michael Traugeot for their contributions to this research project.

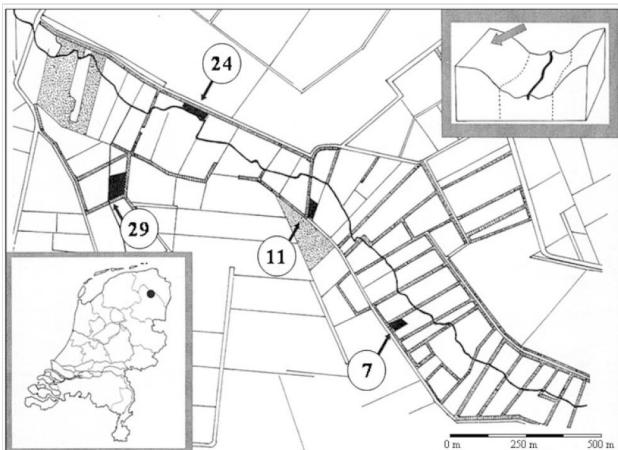

## Author contributions

LH collected the data and started the process of organising and publishing the dataset. LH and GMG further organised and cross-checked the data. LH wrote the R script for transferring the excel files into Darwin Core format. LH published the data on GBIF. GMG and LH wrote the manuscript. Both authors agree with the final version of the manuscript.

**Figure 1.**

Location of the four grasslands in the valley of Anlooërdiepje in the north-eastern part of the Netherlands (see inset below left). The four black arrows point at the four experimental plots, indicated in black. The numbers in circles indicate the number of years the grassland was taken out of agricultural production at the time of sampling in 1996: plot O (7 years since last fertilisation), plot B (11 years since last fertilisation), plot C (24 years since last fertilisation) and plot K (29 years since last fertilisation). On each grassland, a randomly selected rectangle of 30 m by 15 m served as the sampling plot. See Suppl. material 1 for more information on plant composition.

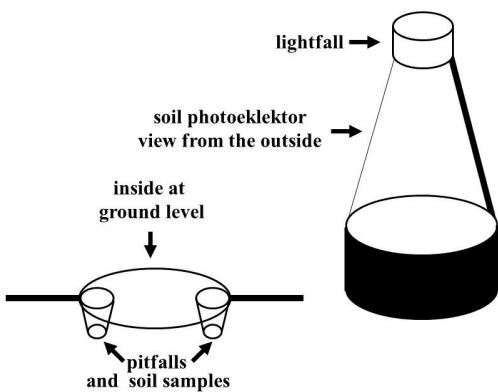

Figure 2.

Sampling was set up with pyramid traps and pitfall traps. The pyramid trap was 80 cm high and had a diameter of 56 cm. Light traps and pitfalls were emptied weekly. Soil samples were taken every two weeks and, at the same time, the light traps and pitfalls were moved to a new location within the experimental plot.

Table 1.

Details on sampling plots (named K, O, C and B), years since extensification (YSE) and trap and soil sample numbers per plot. Note that soil samples are divided into up-soil (top 10 cm) and low-soil (10–20 cm deep) samples, but numbers and plots are the same for both types.

Plot	YSE	Pyramid trap (lf)	Pitfall (pf)	Soil cores (up_soil & low_soil)
O	7	lf4–lf6	pf7–pf12	_soil7–_soil12
B	11	lf10–lf12	pf19–pf24	_soil10–_soil24
C	24	lf7–lf9	pf13–pf18	_soil13–_soil18
K	29	lf1–lf3	pf1–pf6	_soil1–_soil6

**Table 2.**

Environmental variables (a total of 10) can be found in the GBIF Dataset "Macro-invertebrate survey Drentsche Aa 1996". The plant composition is in Suppl. material 1.

Variable	Unit
Wet weight of upper 7.5 cm of the soil core (WWu)	g
Wet weight of the soil core 7.5–15 cm deep (WWI)	g
Dry weight soil of upper 7.5 cm of the soil core (DWu)	g
Dry weight soil of the soil core 7.5–15 cm deep (DWI)	g
Moisture content soil the soil core 0–7.5 cm deep (= 100 * (WWu-DWu)/WWu)	%
Moisture content soil the soil core 7.5–15 cm deep (= 100 * (WWI-DWI)/WWI)	%
Mean precipitation	mm
Maximum air temperature	°C
Minimum air temperature	°C
Mean air temperature	°C
Plant cover (Braun-Blanquet) per species	cover %

Table 3.

Taxonomic list of all species caught during the 1996 sampling programme. The list is organised alphabetically from highest to lowest taxonomic level; first by phylum, then class, order and finally by taxon. Note that taxon contains three levels of identification; subfamily, genus and species, which are in this sequence dealt with within the groups.
