Abstract

Background

Geastrum is the largest genus of Geastraceae and is widely distributed all over the world. Four specimens which belong to *Geastrum* were collected during our scientific expedition to Cangshan Mountain, Yunnan, China. Based on morphological characteristics and phylogenetic analysis, a new species was introduced.

New information

Geastrum suae is characterised by its large basidiomata (height 35–70 mm, diameter 18–37 mm) with long stipe (height 10–45 mm), smooth pink exoperidium and sessile globose endoperidial body. Phylogenetic analysis has been carried out, based on the internal transcribed spacer (ITS) and large subunit ribosomal ribonucleic acid (nrLSU) sequence data. The illustration and description for the new taxa are provided.

Keywords

Geastraceae, ITS, nrLSU, taxonomy, phylogeny

Introduction

Geastrum Pers. is the largest genus of Geastraceae and was established by Persoon (1794). *Geastrum* is commonly known as the earthstars with worldwide distribution and the most species-diverse in the family Geastraceae. Up to now, there are 140 valid species in this genus (Wijayawardene et al. 2022, Zhou et al. 2022, Cabral et al. 2022, Wang and Bau 2023). *Geastrum* clearly differs from *Myriostoma* by a single endodermal stoma (Sousa et al. 2014). Due to the non-splitting ectoderm and the poorly-developed endoperidium being different from *Geastrum*, researchers thought that *Radiigera* is one of the genera closely related to *Geastrum* (Sunhede 1989, de Toledo and Castellano 1996). Later, some studies have found that specimens in *Radiigera* are nested in *Geastrum* (Hosaka et al. 2006, Hosaka and Castellano 2008, da Silva et al. 2013), but the relationship between these two genera has not been studied in depth until Jeppson et al. (2013) classified the species of *Radiigera* into the genus *Geastrum*. Species of this genus are distributed globally, especially in temperate and tropical regions, such as Brazil-Amazon and Europe (de León 1968, da Silva et al. 2013, Jeppson et al. 2013, Zamora et al. 2014, Cabral et al. 2014a, Cabral et al. 2014b, Sousa et al. 2015, Crous et al. 2016, Cabral et al. 2017, Crous et al. 2017, Sousa et al. 2017, Crous et al. 2018a, Crous et al. 2018b, Assis et al. 2019, Finy et al. 2021, Rodrigues et al. 2021). However, the taxonomic relationship under the genus was chaotic (Zamora et al. 2013) until Zamora et al. (2014) divided it into 14 Sections using polygenic analysis, viz. Sect. *Campestris*, *Corollina*, *Elegantly*, *Exareolata*, *Fimbriata*, *Fornicata*, *Geastrum*, *Hariotia*, *Hieronymia*, *Myceliostroma*, *Papillata*, *Pseudoilmbata*, *Schmidelia* and *Trichaster*.

In China, the early systematic report of *Geastrum* can be found in "Fungi in China" (Deng 1963) and "The Confluence of Chinese Fungi" (Dai 1979). Zhou et al. (2007) detailed descriptions of 16 species of *Geastrum* in China in "Flora Fungorum Sinicorum-Geastraceae and Nidulariaceae". Later, three new records and nine new species were reported (Han and Bau 2016, Zhou et al. 2022, Wang and Bau 2023).

Four specimens which belong to *Geastrum* were collected during our scientific expedition to Cangshan Mountain, Yunnan, China. Morphological and phylogenetic analysis revealed that these specimens are the same species and are different from other species in *Geastrum*. Therefore, we introduced it as a new species and provided the detailed description and illustration.

Materials and methods

Morphological description

Macro-morphological descriptions were based on fresh specimens, which were photographed in the field with notes and laboratory supplemental measurements. The colour is compared with the standard colours in the colorhexa website (<https://>

www.colorhexa.com). Micro-morphological data were obtained from the fresh specimens and observed by using a light microscope, following Accioly et al. (2019). Sections were studied at magnification of up to 1000× using a NiKon eclipse Ni microscope and phase contrast illumination and scanning electron microscope (SEM) analysis was done under a Shimadzu SSX–550. Preparation of the material examined under SEM followed da Silva et al. (2011). Microscopic features and measurements were made from slide preparations stained with 5% potassium hydroxide (KOH). Basidiospore features, hyphal system, colour, sizes and shapes were recorded and photographed. Measurements were made using the Image Framework v.0.9.7 to represent variation in the size of basidiospores, 5% of measurements were excluded from each end of the range and extreme values are given in parentheses.

The abbreviation for spore measurements (n/m/p) denote “n” spores measured from “m” basidiocarps of “p” specimens. Basidiospore dimensions (and “Q” values) are given as (a) b–av–c (d), where “a” represents the minimum, “d” the largest, “av” the average “b” and “c” covers a minimum of 90% of the values. “Q” is the length/width ratio of a spore inside view and “Qm” for the average of all spores ± standard deviation. Voucher specimens are deposited in the Herbarium of Cryptogams, Kunming Institute of Botany Academia Sinica (KUN-HKAS).

DNA extraction, PCR amplification and sequencing

The DNA extractions were performed from a small piece of the dried basidioma by using Trelief™ Plant Genomic DNA Kit from Tsingke Biotechnology Co., Ltd (Beijing, China). Two DNA regions were amplified: the internal transcribed spacer nuclear ribosomal DNA (ITS), nuclear ribosomal large subunit (nrLSU) with the primer pairs ITS1F/ITS4 and LR0R/LR5, respectively (Table 1).

PCR reactions (25 µl) contained mixture: 12.5 µl 2X SanTaq PCR Master Mix (including MgCl₂, dNTP, Taq DNA Polymerase, PCR buffer, loading etc.), 1 µl each of primer, 2 µl DNA solution and 9.5 µl sterilised distilled H₂O. The PCR cycling for ITS and nrLSU was as follows: initial denaturation at 94°C for 5 min, followed by 35 cycles at 94°C for 30 sec, 53°C for 30 sec and 72°C for 50 sec and a final extension of 72°C for 10 min. The PCR products were visualised via UV light after electrophoresis on 1% agarose gels stained with ethidium bromide. Successful PCR products were sent to Sangon Biotech Limited Company (Shanghai, China), using forward PCR primers. When sequences have heterozygous INDELS or ambiguous sites, samples were sequenced bidirectionally to make contigs of the amplified regions or verify the ambiguous sites. Raw DNA sequences were assembled and edited in Sequencher 4.1.4 and the assembled DNA sequences were deposited in GenBank (Table 2).

Sequence alignment

Sequence data of two partial loci, internal transcribed spacer region (ITS) and the large subunit ribosomal RNA gene (nrLSU) were analysed. All the sequences, except those

which were obtained from this study, were selected from GenBank for phylogenetic analyses (Table 2). Sequences were aligned using the online version of MAFFT v.7 (<http://mafft.cbrc.jp/alignment/server/>) (Kato and Standley 2013) and adjusted using BioEdit v. 7.0.9 (Hall 1999) by hand to allow maximum alignment and minimise gaps. Ambiguous regions were excluded from the analyses and gaps were treated as missing data. AliView 1.19-beta was used to convert the alignment fasta file to Phylip and Nexus format for phylogenetic analysis. Phylogenetic analyses were obtained from Maximum Likelihood (ML) and Bayesian Inference (BI).

Molecular phylogenetic analyses

The Maximum Likelihood (ML) and Bayesian Inference (BI) methods were used to analyse the combined dataset of ITS and nrLSU sequences. ML analysis was conducted with RAxML-HPC2 on the CIPRES Science Gateway (Miller et al. 2010), involving 100 ML searches; all model parameters were estimated by the programme. The ML bootstrap values (ML-BS) were obtained with 1000 rapid bootstrapping replicates.

Bayesian analysis was performed with MrBayes v.3.2 (Ronquist et al. 2012), with the best-fit model of sequence evolution estimated with MrModelTest 2.3 (Nylander et al. 2008) to evaluate posterior probabilities (PP) (Rannala and Yang 1996, Zhaxybayeva and Gogarten 2002) by Markov Chain Monte Carlo (MCMC) sampling. Six simultaneous Markov chains were run for 100,000,000 generations, trees were sampled every 500th generation and 200,000 trees were obtained. The first 50,000 trees, representing the burn-in phase of the analyses, were discarded, while the remaining 150,000 trees were used for calculating posterior probabilities in the majority rule consensus tree (the critical value for the topological convergence diagnostic is 0.01).

The phylogenetic tree was visualised with FigTree version 1.4.0 (Rambaut 2012) and made in Adobe Illustrator CS5 (Adobe Systems Inc., USA). Sequences derived in this study were deposited in GenBank (<http://www.ncbi.nlm.nih.gov>).

Description

Unexpanded basidiomata 13–28 mm, cylindrical to ellipsoidal, very light grey (#fdfdfd) to very pale red (#ffe6e6) with a slight protrusion, rough. Expanded basidiomata height 35–70 mm, diameter 18–37 mm, deep saccate, **Exoperidium** splitting into 6, arched, not hygrometric, prosthecae length 23–35 mm, diameter 5–13 mm, exoperidium attached to the rhizomorphs. Rhizomorphs with 0.1–5.4 µm hyphae, fibrous and transparent, white (#ffffff). **Mycelial layer** 49.5–59.0 µm, consisting of transparent hyphae (1.0–3.5 µm) with thin walls and no septum, curved. **Fibrous layer** 6.5–16.5 µm, transparent, curved, thick-walled hyphae (1.1–5.0 µm) smooth, transparent to cream (#ffdd0), pure red (#e60000) to dark red (#9a0000) when stained with Congo red. **Pseudoparenchymatous layer** 2.5–19.3 × 2.7–30.4 µm, irregular shape, mycelium is transparent when fresh, pure orange (#ffa500) to moderate pink (#cc6691) when stained with Congo red, the thickness of the pseudoparenchyma layer is about 1.0–1.3 mm, very soft pink (#d98ca0). **Endoperidial body** 11–23 mm, globose, sessile, very light grey (#fdfdfd) to dark grey (#a0a0a0), with lighter reticulation. Endoperidial surface with some protruding hyphae, endoperidium is interwoven by transparent hyphae, fibrous. **Peristome** fibrillose, unpleated, wide conical, with obvious

oral margin ring. Columella obvious very light grey (#f4f4f4 to #e0e0e0). **Eucapillitium hyphae** 1.0–5.5 μm , thick-walled, with distinct cavities, smooth, the ends tapering and are bluntly rounded (Fig. 1).

Basidiospores globose: Holotype (40/2/1) 4.5–5.3–6.0 \times (4.5)5.0–5.4–6.0 μm , $Q = (0.80)0.83\text{--}1.12(1.14)$, $Q_m = 0.98 \pm 0.08$, $n = 40$, including spines truncated at the apex ornamentation, with 0.2–0.5 μm high warts, ornamentation isolated or coalescing crest-like warts. Basidia not observed.

Diagnosis

Geastrum suae is characterised by long stipes and larger basidiomata; Pseudoparenchymatous layer is pink, smooth; globose endoperidial body, grey; the ends of eucapillitium hyphae taper and are bluntly rounded; and they live in groups.

Etymology

The species is named *suae* (Lat.), in memory of the Chinese mycologist Prof. Hong-Yan Su, who kindly helped the authors in many ways and sadly passed away on 3 May 2022 during the preparation of the current paper.

Habit

It grows in groups on the ground in mixed coniferous and broad-leaved forests where there are *Alnus nepalensis* and *Pinus yunnanensis*, with thick humus. Currently, it is known only from Cangshan Mountain.

Analysis

Phylogenetic analysis

Firstly, we constructed the ML tree of *Geastrum* genus, based on ITS (1–540 bp) and nrLSU (541–1498 bp) genes and found that *G. suae* is in Sect. *Mycelioatroma*. The Maximum Likelihood bootstrap values (ML) equal to or greater than 70% are given above each node (Fig. 2), with the Final ML Optimisation Likelihood: -24127.230142. The aligned matrix had 856 distinct alignment patterns, with 6.78% completely undetermined characters or gaps. The base frequency and rate are as follows: A = 0.274187, C = 0.208839, G = 0.265219, T = 0.251755; rate AC = 1.202699, AG = 3.054698, AT = 1.472914, CG = 0.671195, CT = 5.726232, GT = 1.000000; gamma distribution shape: $\alpha = 0.269052$. Therefore, we constructed the ML tree and Bayesian tree of Sect. *Mycelioatroma*, based on ITS and nrLSU genes and clarified the position of *G. suae* in this Section. The dataset is composed of ITS and nrLSU genes, comprising a total of 1478 characters including gaps, ITS (1–591 bp) and nrLSU (592–1478 bp), including 35 taxa with *Myriostoma coliforme* (MA-Fungi 83759) as the outgroup taxon (Fig. 3). The best fit model for the combined 2-gene dataset estimated and applied in the Bayesian analysis was GTR+I+G, Iset nst = 6, rates = invgamma; prset statefreqpr = dirichlet (1,1,1,1). The

phylogenetic analysis of ML and BI produces similar topology. The combined dataset analysis of RAXML generates a best-scoring tree (Fig. 3), with the Final ML Optimisation Likelihood value of -7513.207751. The aligned matrix had 584 distinct alignment patterns, with 21.33% completely undetermined characters or gaps. The base frequency and rate are as follows: A = 0.272494, C = 0.207593, G = 0.257821, T = 0.262093; rate AC = 1.093594, AG = 2.765430, AT = 1.755140, CG = 0.441983, CT = 5.721217, GT = 1.000000; gamma distribution shape: $\alpha = 0.243957$. Bootstrap support values with ML greater than 70% and Bayesian posterior probabilities (PP) greater than 0.95 are given above the nodes (Fig. 3).

Phylogenetic analysis showed that four new collections of *G. suae* clustered together with high bootstrap support and are sister to *G. rubellum* with good bootstrap support (74% ML/ 1 PP Fig. 3).

Discussion

Geastrum suae can be easily recognised by the basidiomata with pink neat, smooth 6-lobed ectoderm, globose sessile endoperidium and longer prosthecae.

In the phylogenetic inferences, *Geastrum suae* is sister to *G. rubellum*, which is known from the biome Tropical and Subtropical Moist Broadleaf Forests in Brazil (Accioly et al. 2019) (Fig. 3). Morphologically, both species share similar characteristics of the mesopodal basidiomata, but *G. rubellum* has reddish to brownish exoperidium with longer exoperidium hairs. *G. suae* hardly has such hairs and the reddish pseudoparenchymatous layer in *G. rubellum* also clearly differentiates *G. suae*. Not only that, but *G. rubellum* also has reddish to brownish exoperidium with a verrucose to hairy mycelial layer, while the exoperidium of *G. suae* is almost smooth. Their size is different, the expanded basidiomata saccate of *G. rubellum* being 10 mm high \times 8.5–30 mm wide, while *G. suae* is 35–70 mm high \times 18–37 mm wide. The warts on the basisiospore of *G. suae* are shorter than those of *G. rubellum*. The pseudoparenchymatous layer of *G. rubellum* is pure (or mostly pure) pink (#fa007d) when fresh, brownish-grey when dried, but is very pale red (#ffccd5) for *G. suae*. The ITS comparison between our specimen (KUN-HKAS 123795) and *G. rubellum* (LIP: PAM/MART 12.100) revealed a 53 bp difference in a total of 542 bp. The nrLSU comparison between *G. suae* (KUN-HKAS 123795) and *G. rubellum* (LIP: PAM/MART 12.100) revealed 11 bp difference in a total of 809 bp (Accioly et al. 2019). It is worth noting that *G. rubellum* is distributed in the Neotropics (Accioly et al. 2019). Combined with the above analysis, we introduce *Geastrum suae* as a new species.

Acknowledgements

The research was financed by the National Natural Science Foundation of China (Project No. 32060006). This study was also supported by the Yunnan Fundamental Research Projects (grant No. 202201BC070001). The authors thank Kai Wang for the assistance in

sample collection, thank Dan-Feng Bao for sharing the knowledge of phylogeny and thank Long-Li Li for giving instruction for microscopic measurement.

Figure 1.

Geastrum suae (KUN-HKAS 123795, holotype). **a** fresh unexpanded fruiting bodies; **b, c** fresh mature fruiting bodies; **d** mycelial layer, fibrous layer and pseudoparenchymatous layer; **e** hyphae of mycelial layer; **f** pseudoparenchymatous layer (cells in the stack); **g, h** eucapillitium hyphae; **i-k** basidiospores (LM); **l-n** basidiospores (SEM). Scale bars: a = 10 mm; b, c, e = 20 mm; d = 80 μ m; f, g, i-k = 10 μ m; h = 70 μ m; l = 1 μ m; m, n = 500 nm.

Figure 2.
Phylogenetic tree of *Geastrum* species and related taxa, based on ITS and nrLSU sequence data.

Figure 3. Phylogenetic tree of the new *Geastrum* species and related taxa which belong to sect. *Myceliostroma*, based on ITS and nrLSU sequence data. Branches are labelled with bootstrap values (ML) higher than 70% and posterior probabilities (PP) higher than 0.95. The new species are shown in red bold.

Table 1.

Amplification primers information used in this study.

Gene	Primer	Primer sequence (5'-3')	References
ITS	ITS1F	CTTGGTCATTTAGAGGAAGTAA	Gardes and Bruns (1993)
	ITS4	TCCTCCGCTTATTGATATGC	White et al. (1990)
nrLSU	LR0R	ACCCGCTGAACTTAAGC	Vilgalys and Hester (1990)
	LR5	ATCCTGAGGGAACTTC	Vilgalys and Hester (1990)

Table 2.

Species, specimens, Collection locality and GenBank accession numbers of sequences used in this study (newly-generated sequences are indicated in bold).
